

The Rock Cycle and the Formation of Minerals

The surface of the Earth is in a constant state of transformation. While these changes often occur on timescales far beyond human perception, they shape the landscapes we inhabit and influence the resources we use daily. Central to this dynamic Earth system is the rock cycle—a continuous, natural process by which rocks are created, transformed, destroyed, and reformed. Through this cycle, rocks move between three primary types—igneous, sedimentary, and metamorphic—each with distinct characteristics and formation pathways. Closely intertwined with this cycle is the formation of

the Earth's surface, it crystallizes into intrusive or plutonic igneous rocks such as granite. These rocks often exhibit coarse-grained textures due to the prolonged growth of mineral crystals. In contrast, when lava cools rapidly at the surface, it forms extrusive or volcanic rocks like basalt, characterized by fine-grained or glassy textures. The type of igneous rock that forms depends not only on the cooling rate but also on the composition of the magma, which determines the types of minerals that crystallize during solidification.

As rocks are exposed to the elements at or near the surface, they begin to break down through weathering and erosion. Physical weathering,

such as freeze-thaw cycles or abrasion by wind and water, disintegrates rocks into smaller particles. Chemical weathering, on the other hand, alters the mineral composition of rocks through processes like oxidation or hydrolysis. These particles, now sediments, are transported by rivers, wind, or glaciers and eventually deposited in layers. Over time, pressure from overlying materials and the gradual removal of water cause these sediments to compact and cement together, forming sedimentary rocks. Examples include sandstone, formed from compacted sand, and limestone, composed primarily of calcium carbonate from biological debris.

Sedimentary rocks often contain valuable information about Earth's

particular interest to geologists and paleontologists seeking to reconstruct past environments.

When existing rocks are subjected to significant changes in temperature, pressure, or chemical environment—often deep within the Earth's crust—they undergo metamorphism, a process that alters their mineral composition and texture without melting them. The resulting metamorphic rocks, such as marble or schist, retain some features of their parent rock but display new mineral assemblages or foliation patterns due to the reorientation of minerals under stress. For example, shale, a sedimentary rock, may metamorphose into slate through low-

grade metamorphism, and eventually into schist under more intense conditions.

At any point in the rock cycle, rocks can be recycled into other types. Igneous rocks may be weathered into sediments, metamorphic rocks may melt into magma, and sedimentary rocks can be buried and transformed under pressure. This cyclic nature highlights the interconnectedness of geological processes and the long-term evolution of the Earth's crust.

Minerals, which are the building blocks of rocks, form under specific environmental conditions during the different stages of the rock cycle. A

Minerals can crystallize directly from molten magma, precipitate from solution, or form through changes in pressure and temperature during metamorphism. For instance, quartz and feldspar, two of the most common minerals in the continental crust, typically crystallize from cooling magma. Calcite, the main mineral in limestone, often precipitates from marine water. During metamorphism, new minerals such as garnet or kyanite may form as atoms rearrange into more stable structures under changing conditions.

The economic importance of minerals cannot be overstated. Many of the materials essential for modern life—from the metals used in

electronics to the nutrients in fertilizers—originate from mineral deposits. Ore minerals, which contain valuable elements like copper, gold, or iron, are mined for industrial and technological purposes. Understanding how these minerals form and accumulate helps guide exploration and sustainable extraction.

Moreover, the rock cycle plays a critical role in regulating Earth's carbon cycle and climate. Sedimentary rocks can sequester carbon over geologic timescales, locking it away in the form of carbonate minerals or organic-rich shale. Conversely, volcanic eruptions associated with igneous activity release carbon dioxide into the atmosphere, influencing long-term climate patterns. These complex

analysis. These methods allow scientists to determine the composition and origin of rocks, date geological events, and model Earth's internal processes. Fieldwork also remains an essential component of geological study, as rock formations in their natural settings reveal relationships and histories that laboratory samples alone cannot convey.

In conclusion, the rock cycle is a fundamental concept in Earth science that illustrates the dynamic nature of our planet's crust. It encompasses the formation and transformation of rocks and minerals through an array of physical and chemical processes. From the depths of molten

magma chambers to the pressures of mountain-building collisions, the cycle continues to shape our planet. A deep understanding of this cycle not only provides insight into Earth's past but also equips us to better manage its resources and anticipate future geological changes.

Questions

1. The word “**solidification**” in paragraph 2 is closest in meaning to:

- A. evaporation
- B. freezing
- C. melting

How to inform: Write it in the Skype chat or the comments section when making a reservation.

- A. The amount of quartz present
- B. Whether it was formed on land or in water
- C. The speed and location of magma cooling
- D. The pressure applied during formation

3. The word “**disintegrates**” in paragraph 3 is closest in meaning to:

- A. floats
- B. rotates
- C. breaks apart
- D. expands

4. According to paragraph 4, why are sedimentary rocks important to geologists?

- A. They contain metal ores essential for human use.
- B. They are the most abundant rocks in the Earth's mantle.
- C. They preserve evidence of past environments and life.
- D. They are more resistant to weathering than other rocks.

5. The word “**assemblages**” in paragraph 5 is closest in meaning to:

A. individual parts

B. collections

sentence in paragraph 6?

“At any point in the rock cycle, rocks can be recycled into other types.”

- A. All rock types can return to magma when exposed to high heat.
- B. Rocks are often replaced by newly formed minerals.
- C. Rocks can change into different types at various stages in the cycle.
- D. Each rock type is made from broken pieces of other rocks.

7. The word “**dominates**” in paragraph 7 is closest in meaning to:

A. increases

B. limits

- C. controls
- D. is most common in

8. According to paragraph 8, why is understanding mineral formation important for industry?

- A. It helps scientists predict volcanic eruptions.
- B. It reveals how mountains are formed.
- C. It guides mineral exploration and sustainable extraction.
- D. It reduces the cost of drilling operations.

9. What can be inferred from paragraph 9 about how the rock cycle

How to inform: Write it in the Skype chat or the comments section when making a reservation.

- C. Rocks play no role in global environmental systems.
- D. The formation of sedimentary rocks increases greenhouse gas emissions.

10. In the article, all of the following are mentioned as factors that can lead to rock transformation **EXCEPT**:

- A. changes in temperature
- B. exposure to wind and water
- C. melting and recrystallization
- D. biological digestion of rock

Answers

1. The word “**solidification**” in paragraph 2 is closest in meaning to:

✓ Correct Answer: B. freezing

2. According to paragraph 2, what determines whether an igneous rock is intrusive or extrusive?

✓ Correct Answer: C. The speed and location of magma cooling

3. The word “**disintegrates**” in paragraph 3 is closest in meaning to:

完全版テキストはレッスン前に“教材名”を講師に伝えてください。

How to inform: Write it in the Skype chat or the comments section when making a reservation.

✓ Correct Answer: C. They preserve evidence of past environments and life.

5. The word “**assemblages**” in paragraph 5 is closest in meaning to:

✓ Correct Answer: B. collections

6. Which of the following best expresses the essential meaning of the sentence in paragraph 6?

✓ Correct Answer: C. Rocks can change into different types at various stages in the cycle.

7. The word “**dominates**” in paragraph 7 is closest in meaning to:

✓ Correct Answer: D. is most common in

8. According to paragraph 8, why is understanding mineral formation important for industry?

✓ Correct Answer: C. It guides mineral exploration and sustainable extraction.

9. *What can be inferred from paragraph 9 about how the rock cycle*
